Pystoch Basics

For pystoch to work-

- framesets.ini: This file contains information about folded data. There is parameter called process that need to be true only for those baseline for which we like to create dirty map. For this tutorial purpose it will be only O2_HL . You need to go this file and change path from
`/content/drive/MyDrive/Pystoch_Tut/O2_HL/IGWN-FoldedData-v1-O2_H1L1_compressed.hdf5` to where your folded data is.
- parameters.ini: This files take range of frequency and pixels of sky in which we like create dirty map and as well path to folded data folder. You need to make sure multi_threads do not exceed your computer limit.
- Make sure you have folders where output need to be saved like output,tmp and Clean_map.
- To avoid any kind of issue for those using local machine, a environment need to set up. The following steps need to be taken to set up the environment.

1. Create a new env

```
conda create -n pystoch python=3.11
```

2. Activate the environment

```
conda activate pystoch
```

3. Get important dependencies

```
conda install -c conda-forge healpy scipy matplotlib h5py numpy
```

4. For MacOS, to make multiprocessing work, you need to uncomment the following lines in the pystoch.py file (available in the shared Google Drive).

```
import multiprocessing as mp
mp.set_start_method("fork", force=True)
```

- In pystoch.py change path for framesets.ini and parameters.ini
